(a) Enrolment / probe split

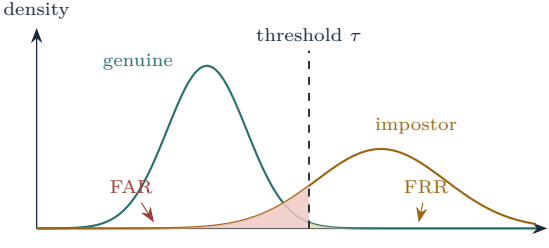

The same split is used for Map A and Map B. Primary result: mean over five seeded splits (0–4); a fixed first-half/second-half split is kept only as a session-bias check. The pair-level analysis in the main text uses a different protocol (all unordered pairs), so its AUC is not directly comparable with the operating points below. All identities are known and enrolled; there are no unknown-identity probes.

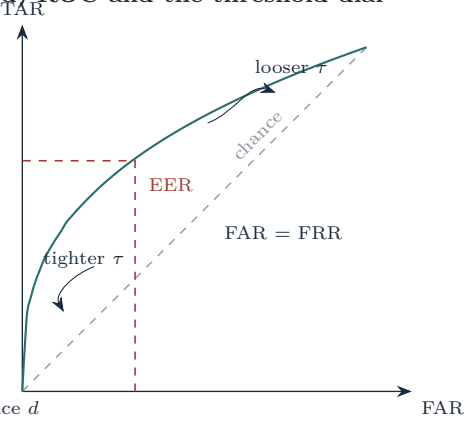

(b) Trials and decision

(c) Score distributions

(d) ROC and the threshold dial

As τ increases the system accepts more: FAR rises and FRR falls; lowering τ is tighter. The EER is the operating point where the two error rates are equal.
