(a) Enrolment / probe split

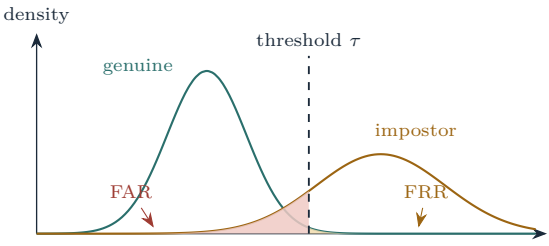

The same split is used for Map A and Map B. Primary result: mean over five seeded splits (0–4); a fixed first-half/second-half split is kept only as a session-bias check. The pair-level analysis in the main text uses a different protocol (all unordered pairs), so its AUC is not directly comparable with the operating points below.

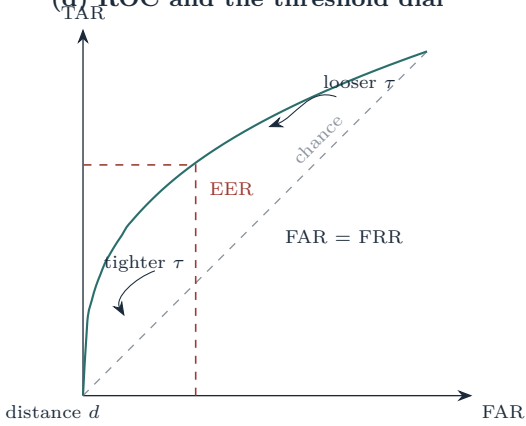

(b) Trials and decision

(c) Score distributions

(d) ROC and the threshold dial

As τ decreases the system accepts more: FAR rises and FRR falls. The EER is the operating point where the two error rates are equal.
